About this Guide

Welcome to Qualys Container Security! We’ll help you get acquainted with the Qualys solutions for securing your Container environments like Images, Containers and Docker Hosts using the Qualys Cloud Security Platform.

About Qualys

Qualys, Inc. (NASDAQ: QLYS) is a pioneer and leading provider of cloud-based security and compliance solutions with over 9,300 customers in more than 100 countries, including a majority of each of the Forbes Global 100 and Fortune 100. The Qualys Cloud Platform and integrated suite of solutions help organizations simplify security operations and lower the cost of compliance by delivering critical security intelligence on demand and automating the full spectrum of auditing, compliance and protection for IT systems and web applications. Founded in 1999, Qualys has established strategic partnerships with leading managed service providers and consulting organizations including Accenture, BT, Cognizant Technology Solutions, Fujitsu, HCL Comnet, HPE, Infosys, NTT, Optiv, SecureWorks, Tata Communications, Verizon and Wipro. The company is also founding member of the Cloud Security Alliance (CSA). For more information, please visit www.qualys.com

Qualys Support

Qualys is committed to providing you with the most thorough support. Through online documentation, telephone help, and direct email support, Qualys ensures that your questions will be answered in the fastest time possible. We support you 7 days a week, 24 hours a day. Access online support information at www.qualys.com/support/.
Container Security Overview

Qualys Container Security provides discovery, tracking, and continuously protecting container environments. This addresses vulnerability management for images and containers in their DevOps pipeline and deployments across cloud and on-premise environments.

With this version, Qualys Container Security supports:
- Discovery, inventory, and near-real time tracking of container environments
- Vulnerability analysis for images and containers
- Integration with CI/CD pipeline using APIs (DevOps flow)
- Uses new ‘Container Sensor’ – providing native container support, distributed as docker image
Docker Image

A Docker image is a read-only template. For example, an image could contain an Ubuntu operating system with Apache and your web application installed. Images are used to create Docker containers. Docker provides a simple way to build new images or update existing images, or you can download Docker images that other people have already created. Docker images are the build component of Docker.

An image is a static specification what the container should be in runtime, including the application code inside the container and runtime configuration settings. Docker images contain read-only layers, which means once an image is created it is never modified.

Image is tracked within Qualys Container Security module using Image Id and also a unique identifier generated by Qualys called Image UUID.

Docker Registry

Docker registries hold images. These are public or private stores from which you upload or download images. The public Docker registry is provided with the Docker Hub, Quay.io or from cloud providers like AWS ECR, Azure Container Registry or Google Container Registry. It serves a huge collection of existing images for your use. These can be images you create yourself or you can use images that others have previously created. Docker registries are the distribution component of Docker.

Docker Containers

Docker containers are similar to a directory. A Docker container holds everything that is needed for an application to run. Each container is created from a Docker image. Docker containers can be run, started, stopped, moved, and deleted. Each container is an isolated and secure application platform. Docker containers are the run component of Docker.

A running Docker container is an instantiation of an image. Containers derived from the same image are identical to each other in terms of their application code and runtime dependencies. But unlike images that are read-only, each running container includes a writable layer (a.k.a. the container layer) on top of the read-only content. Runtime
changes, including any writes and updates to data and files, are saved in the container layer only. Thus multiple concurrent running containers that share the same underlying image may have different container layers.

Containers are tracked within Qualys Container Security module using Container Id and also a unique identifier generated by Qualys called Container UUID.

**Docker Host**

Hosts or servers running docker daemon and hosting containers and images. Qualys tracks them as Host Assets, collects the metadata including IP address, DNS and other attributes of the Host. A host in Qualys is identified by a unique identifier Host UUID. The UUID is also stored in a marker file under /usr/local/qualys directory by the Agent or a scan with authentication via a Scanner Appliance.

**Qualys Container Sensor**

The new sensor from Qualys designed for native support of Docker environments. Sensor is packaged and delivered as a Docker Image. Download the image and deploy it as a Container alongside with other application containers on the host.

These are docker based, can be deployed on hosts in your data center or cloud environments like AWS ECS, Azure Container Service or Google Container Service. Sensor currently is only supported on Linux Operating systems like CentOS, Ubuntu, RHEL, Debian and requires docker daemon of version 1.12 and higher to be available.

Since they are docker based, the sensor can be deployed into orchestration tool environments like Kubernetes, Mesos or Docker Swarm just like any other application container.

Upon installation, the sensor does automatic discovery of Images and Containers on the deployed host, provides a vulnerability analysis of them, and additionally it monitors and reports on the docker related events on the host. The sensor container runs in non-privileged mode. It requires a persistent storage for storing and caching files.
Currently, the sensor only scans Images and Containers, for getting a vulnerability posture on the Host, you would require Qualys Cloud Agents or a scan through Qualys Virtual Scanner Appliance. Currently doesn’t do inventory collection specific to orchestration tools and identifies the nodes/slaves as just docker hosts.
Get Started

Follow the steps to get started with Container Security.

Qualys Subscription and Modules required

You would require “Container Security” (CS) module enabled for your account. Additionally, in order to get vulnerabilities for the hosts that run the containers, you would need to enable Vulnerability Management (VM), either via Scanner Appliance or Cloud Agent.

System support

Container Security supports these systems running Docker version 1.12 and above.

- Ubuntu
- Red Hat Enterprise Linux
- Debian
- CentOS

Deploying Container Sensor

Log into your Qualys portal with your user credentials. Select Container Security from the module picker.

As a first time user, you’ll land directly into the Getting Started page.
Click “Download and Install Qualys Container Sensor”

Download the QualysContainerSensor.tar.xz file and run the commands generated directly from the screen on the docker host. Note the requirements for installing the sensor, the sensor needs a minimum of 1 GB persistent storage on the host.

A quick overview of the “installsensor.sh” script command line parameters options:

- **ActivationId**: Activation Id for the container sensor, auto-generated based on your subscription.
- **CustomerId**: Qualys subscription’s customerId, auto-generated based on your subscription.
- **Storage**: Directory where the sensor would store the files. Default: /usr/local/qualys/sensor/data. Create it if not already available or you can specify a custom directory location.
- **ImageFile**: Location of the Sensor ImageFile, defaults to the local directory [Optional]
- **LogLevel**: Configuration to set the logging level for sensor, accepts 0 to 5. [Optional]
- **HostIdSearchDir**: Directory to map the marker file created by Qualys Agent or Scanner appliance on the host, update if modified [Optional]
- **ConcurrentImageScan**: Number of concurrent images scan thread pool size. [Optional]
- **ConcurrentContScan**: Number of concurrent container scan thread pool size. [Optional]
- **Proxy**: IPv4/IPv6 address or FQDN of the proxy server [Optional]
- **ProxyCertFile**: Proxy certificate file path [Optional]
  
  ProxyCertFile is applicable only if Proxy has valid certificate file. If this option is not provided then Sensor would try to connect to the server with given https Proxy settings only.

  If only ProxyCertFile is provided without Proxy then Sensor would simply ignore the ProxyCertFile and it would try to connect to the server without any https proxy settings.

- **--silent or -s**: Parameter to run installsensor.sh in non-interactive mode.[Optional]

**Proxy Support**

The install script asks for proxy configuration. You need to provide the IP Address/FQDN and port number along with the proxy certificate file path. For example,

Do you want connection via Proxy [y/N]: y  
Enter Https Proxy settings [<IP Address>:<Port #>]: 10.xxx.xx.xx:3xxx  
Enter Https Proxy certificate file path: /etc/qualys/cloud-agent/cert/ca-bundle.crt

Your proxy server must provide access to the Qualys Cloud Platform (or the Qualys Private Cloud Platform) over HTTPS port 443. Go to Help > About to see the URL your hosts need to access.

**Sensor network configuration**

The sensor is pre-configured with the Qualys URL and the subscription details it needs to communicate to. In order for the sensor to communicate to Qualys, the network configuration and firewall needs to provide accessibility to Qualys domain over port 443.

After successful installation of the Sensor, the sensor is listed under Configurations > Sensors where you can see its version, status, etc. and access details.

Additionally, you can Download the sensor from the link under Configurations > Sensors.
Securing Container Assets

Asset Inventory

Upon installation of the sensor, it automatically scans the host for the images and containers that are present on the host. The inventory and the metadata of the inventory is pushed to Qualys portal.

Dashboard

Container security application provides out-of-the-box default Security Overview Dashboard providing summary of inventory and security posture across container assets. The default dashboard provides

- An inventory list of Images, Containers and the Sensors
- Vulnerability summary for all of the images
- Vulnerability summary for all the containers
- Events and their trend over the last 24 hrs
- Listing of the most popular Images and Containers by Labels

Asset Details

Assets tab list the Images and Containers discovered along with their metadata information like ports, networks, services, users, installed software, etc. The assets are listed along with their associations like associated containers and hosts for an image, other containers from the same parent image. Users can search for images and containers based on their attributes.
Clicking View Details in the Quick Actions menu for an image in the Assets > Images tab, displays comprehensive information about the image.

You can view detailed information about that image, its associations with containers, rogue containers, and hosts. Installed Software panel displays software having vulnerabilities, and for which fixes (patches) are available. You can view the vulnerability information such as confirmed vulnerabilities, potential vulnerabilities with their severity. The Layers panel displays a list of layers the image is made of.
Container Details

Clicking View Details in the Quick Actions menu for a container in the Assets > Containers tab, displays comprehensive information about the container.

You can view detailed information about that container, its associations with an image, rogue containers, and hosts. Installed Software panel displays software having vulnerabilities, and for which fixes (patches) are available. You can view the vulnerability information such as confirmed vulnerabilities, potential vulnerabilities with their severity. Services/Users panel displays the list of services available in the container and users associated with the container.

Host Details

Access the details page for a host from the Sensor details page. Asset Details view displays information about the host on which the sensor is deployed. Besides system, network, and port information, the Asset Details view also displays a list of software installed on the
host, vulnerabilities present, certificates, and Threat Protection RTIs (when Qualys TP app is enabled). Container Security panel shows all containers installed on the host, their status, and the images from which the containers are spawned.

### Vulnerability scanning of Docker Images

The docker images are scanned to check the presence of any vulnerabilities by the Qualys container sensor. The vulnerabilities panel in Image Details provides a list of vulnerabilities with Severity along with their QIDs.

Qualys scans the docker images for vulnerabilities not through static analysis but via a non-static method, where it looks at the Image as a complete entity. This process is more effective and has lesser false positives (FP) than the more commonly used Static Analysis.

Docker Images are found distributed across the environment from developer laptops, build systems, Image Registry to being cached on the docker hosts running Containers. To scan for vulnerabilities you would need the Container Sensor deployed on the host asset.

To get an inventory of the images and scan them for vulnerabilities, deploy the container sensor on the host. Refer to [Deploying Container Sensor](#) for the install instructions and system requirements.
On the local host or laptops

To get an inventory of the images and scan them for vulnerabilities, deploy the container sensor on the local host. Refer to Deploying Container Sensor for the install instructions and system requirements.

To deploy the Sensor on the Mac laptops, there are additional install steps - follow the instructions in the Appendix. See Installing the sensor on a MAC.

Upon Installation the sensor automatically detects the images, and provides -inventory and vulnerability scans of the image.

In the CI/CD pipeline

Doing a complete check of vulnerabilities in an image during the build time ensures a lot cleaner operating environment. Qualys Container Security provides a plugin for Jenkins to get an vulnerability analysis of images in the build environment. (Learn more how to configure and use the plugin - Qualys Vulnerability Analysis Plugin for Jenkins) If you are using other tools you can use the REST APIs available to perform vulnerability analysis on the images.

To start, deploy the Container Sensor on the Build host where the images are being created. The sensor upon install would automatically trigger a vulnerability analysis of the new images found. Use the API or the plug-in to look for vulnerabilities in the Images. If you are in Jenkins env, , the plug-in would provide detail list of the vulnerabilities and its details directly within the plug-in, you could optionally access your Qualys subscription to view the full report.

In the Registry

Currently, the Qualys Container Sensor doesn't automatically poll or pull images to do an analysis. Rather you would be needed to deploy the sensor on the host that is configured to pull images from the registry. Either manually or via a cron pull the new images to the host. The sensor does an automatic analysis as soon as it finds a new image. Use the APIs or the Qualys portal to query for the vulnerabilities identified.
Vulnerability scanning of Docker Containers

The containers are scanned to check the presence of any vulnerabilities within the containers. The Vulnerabilities panel in Container Details provides a list of vulnerabilities with Severity along with their QIDs.

**Good to know!**

**Rogue Containers** are those which contain vulnerabilities or software, not found in the image from which the container is spawned.

**Rogue Vulnerabilities** are classified as either New, Fixed or Varied. New are those which are newly found on the containers, but were not present in the image from which the container is spawned. Fixed, are the vulnerabilities that are not found in the container but in the image. Varied, are the vulnerabilities that are found in both Containers and Images but the detection varies between them.

**Rogue Software** are classified as new or removed. New, software which are found in the Container but not in the image from which the container is spawned. Fixed, Software not seen in the Container but is present in the parent Image.

**Vulnerability scanning of Docker Hosts**

Container Security Sensor scans Images and Containers for vulnerabilities, and not the actual host machine. You can scan the host via Scanner Appliance or Cloud Agent. Configurations required on the host for using the Cloud Agent are independent of the Sensor. For example, proxy configuration.
Working with Events

The Events tab displays a log for all activities that you perform on the images and containers installed on the host. These activities could be tagging of images, create, destroy or commit containers. The events list displays the timestamp of the event along with the event ID, type, and the host on which the activities took place.
Container Security API

All features of the Container Security are available through REST APIs.

You can directly access the Swagger UI from the following URL

https://<QualysURL>/csapi/swagger-ui.html

For example, if your account is on US Platform 2

For information on what API Server URL to use, see the section “API Server URL” in the Qualys API Quick Reference Guide.

Authentication

Click Authorize to provide the user name and password for authenticating to the Qualys Cloud Platform before trying out the APIs.
Administration

Sensor updates

When an update is available you'll see “Update Available” next to the sensor name.

Container sensor update is otherwise automatic, however if you are currently using the beta version of the sensor you need to update to the latest sensor version manually. Automatic update kicks off once you are on a version higher than the beta.

To manually update the sensor from beta to the latest version, download the QualysContainerSensor.tar.xz file from Qualys Cloud Portal and then run the following commands directly from the screen on the docker host.

Untar the sensor package:

```bash
sudo tar -xvf QualysContainerSensor.tar.xz
```

Launch the new sensor:

```bash
sudo ./installsensor.sh ActivationId=5e7e422a-a1ca-403f-9274-506822dc5b28 CustomerId=a8cf7043-0245-6f1d-82f8-97f78465b93 Storage=/usr/local/qualys/sensor/data -s
```

Enter Y at the prompt asking you to upgrade 'Qualys-Container-Sensor' from version x.x.x to x.x.x.

The install script asks for proxy configuration. If you want to configure proxy, see Proxy Support.

Note: Once you have upgraded from the beta version to a higher version, future updates of Sensor are automatic.
How to uninstall sensor

The QualysContainerSensor.tar.xz file (which you download for sensor installation from Qualys Cloud Platform) has the script `uninstallsensor.sh` for uninstalling the sensor.

To uninstall a sensor:

If the docker host is configured to communicate over docker.sock, use the following command:

```
./uninstallsensor.sh -s
```

If the docker host is configured to communicate over TCP socket then provide the address on which docker daemon is configured to listen:

```
./uninstallsensor.sh DockerHost=<IPv4 address or FQDN>:<Port#> -s
```

For example,

```
./uninstallsensor.sh DockerHost=10.115.27.54:3128 -s
```

Follow the on-screen prompts to uninstall the sensor. Qualys recommends not to clear the persistent storage.
Troubleshooting

Check sensor logs

The sensor log file is located at (by default):
/usr/local/qualys/sensor/data/logs/qpa.log

Diagnostic script

Qualys provides a script to collect diagnostic information about the sensor. You must run the script on the host on which you want to collect the diagnostic information from.

The diagnostic script is present in the QualysContainerSensor.tar.xz that you downloaded for installing the sensor.

The script is called Sensor_Diagnostic_Script.py. You must have Python installed on the host in order to run the script. The script collects the following information from the host and puts it in a tar file called SensorDiagnostic.tar. You can send that file to Qualys Support for further assistance.

The SensorDiagnostic.tar includes ‘ScanInfo.json’, ‘qpa.log’ of qualys-container-sensor from given persistent storage, docker logs of qualys-container-sensor, and all information described below in the ‘SensorDiagnostic.log’ file. If ‘ScanInfo.json’ and Sensor logs are not available on the Docker host then this script creates empty ‘ScanInfo.json’ and qpa.log files, and appends “File not found” to them.

- Operating System Information (Type of OS i.e. Linux or Mac and other details)
- Proxy Configuration (Type of proxy set e.g. system, docker, cloud-agent proxy)
- CPU Architecture (Details about model, CPUs, cores, etc)
- RAM Usage (Memory allocation and utilization on host)
- Docker Version (Docker version installed on host)
- Socket Configuration (Docker socket configuration on host e.g. TCP/unix domain)
- Number of docker images (Count of all docker images and their details)
- Number of docker containers (Count of all docker containers and their details)
- CPU and Memory usage of running containers (First result of all resource usage statistics)
Sensor crashes during upgrade

Use installsensor.sh to reinstall Qualys container sensor keeping the "Storage" value as it was for earlier Sensor. This will ensure that the new sensor will not be marked as another Sensor and will simply upgrade the existing one.

For help on install command, see Deploying Container Sensor.

Note: At any given point in time, DO NOT delete the persistent storage. Else, the sensor deployed thereafter will be marked as a new sensor.

What if sensor restarts?

The Sensor is designed to handle restart scenarios and will continue functioning normally after restart. No customer intervention is needed until the sensor crashes.

Note: The Qualys container sensor will fail to restart if it has exited due to a fatal error before the docker host/service restarts.

Known Issues and Limitations

Known limitations include Automated Registry Scanning, Deletion of Sensors from the pages, and raising of alerts for Events. These features are planned to be added soon.

The sensor only works for Docker and in Linux env.
**Appendix**

**Qualys Vulnerability Analysis Plugin for Jenkins**

Qualys Container Security provides a plugin for Jenkins to get the security posture for the docker images built via the tool. The plugin can be configured to fail or pass the docker image builds based on the vulnerabilities detected.

**What you’ll need**
- A valid Qualys subscription with the Container Security application activated.
- Access to Qualys Container Security application API endpoint from your build host.
- Requires the container sensor to be installed on the jenkins build host.

**Install the Plugin**

1. Download the plugin from here.

2. Upload the plugin to your Jenkins tool. Go to Manage Jenkins > Manage Plugins > Advanced > Upload Plugin, then restart it.

**Start Using the Plugin**

This plugin provides a build step and a post-build action. You can use it with pipeline type projects (for CI/CD pipeline) as well as freestyle projects. We’ll describe both in the sections that follow.

- Pipeline Project
- Freestyle Project
Pipeline Project

With pipeline projects, you provide the docker image Id(s) to the plugin via a command argument. Use our Snippet Generator to generate this command, and then copy/paste it into your pipeline script (Jenkinsfile).

What are the steps?

In the Snippet Generator, select “getImageVulnsFromQualys - Get Image Vulns From Qualys” and then provide configuration details including (1) API login information, (2) data collection frequency, and (3) build fail conditions. (4) Click Test Connection to verify that the plugin can call the Qualys Container Security API. (5) When you're ready, click Generate Pipeline Script to get the script command.

For information on what API Server URL to use, see the section “API Server URL” in the Qualys API Quick Reference Guide.

Define docker image Ids

You'll notice an argument called imageIds. Set this to the docker image Ids you want to report on. The plugin will only pull a report for the image Ids you specify.

Enter a single string value like imageIds: ‘a1b2c3d4e5f6’ or a comma-separated list like imageIds: ‘a1b2c3d4e5f6,abcdef123456’. You can also define docker image Ids in a variable and specify the variable as the value.

You can provide image ids through an environment variable. Get the image ids of the images programmatically created in earlier stages of the build and provide these ids in the ‘imageIds’ argument. For example, in pipeline script, you can get the image ids by executing shell script and store it in environment variable. And then use the same environment variable in ‘imageIds’ argument to provide the image ids.
Freestyle Project
For Freestyle projects you can use a POST-BUILD step provided by the plugin.

You'll provide the docker image Id(s) using the environment variable. Note – The variable name must be defined correctly or the plugin will not work. When Jenkins executes the post-build steps the plugin will only pull a report for the image Ids you’ve specified.

What are the steps?
In Post-Build Actions, select “Get docker image vulnerabilities from Qualys”. This will open a form similar to the one shown for pipeline projects. Provide configuration details and test the connection to make sure it’s successful.

Somewhere in your build steps you must set the IMAGE_ID environment variable to the docker image Ids you want to report on. IMAGE_ID can be a single string value like 'a1b2c3d4e5f6' or a comma-separated list like 'a1b2c3d4e5f6,abcdef123456'.

View Your Qualys Report
In either case - pipeline project or freestyle project - the plugin will generate one report for each docker image in the build. In other words, multiple image Ids will result in multiple report links.
Click any report link to see vulnerability details for the docker image.

The Build Summary provides a dashboard view of your security posture. Go to Vulnerabilities for a list of detected QIDs, Installed Software to see software detected on the docker image, and Layers to view a list of layers the image is made of.

**Debugging and Troubleshooting**

**HTTP codes in API response**

All API calls and their responsese are logged by the plugin and are visible in the Console Output. Here are the HTTP response codes you may see during plugin execution.

<table>
<thead>
<tr>
<th>Code</th>
<th>Error</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>204</td>
<td>No content</td>
<td>Qualys sensor is processing data. You’ll see 200 OK when complete.</td>
</tr>
<tr>
<td>200</td>
<td>OK</td>
<td>You would see this code in two situations: 1) You might have received partial data from Qualys where image details are available but vulnerability data is not available. 2) Vulnerability data is also available. This is usually the last call, after which the thread for that image Id stops.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error</td>
<td>Qualys service is down or there was an issue processing data.</td>
</tr>
<tr>
<td>400</td>
<td>Bad request</td>
<td>Qualys API server is unable to understand the request.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized</td>
<td>The credentials used for Qualys API server are incorrect or the user does not have access to the APIs.</td>
</tr>
</tbody>
</table>
If you don't see any API calls being made...

Make sure you’re correctly passing image Ids to the plugin. When the plugin starts the execution, it will print the image Ids provided and you can see this in the Console Output. Check that the docker image Ids you provided are printed.

Plugin times out, no report seen

The plugin is designed to keep polling the Qualys API until the configured timeout period is reached. If it does not get vulnerability data from Qualys within this period, it stops. In this case, the plugin will fail the build only if you have set any fail-on conditions. Otherwise, it will not fail the build. You will not see any report links since the plugin could not get vulnerability data, and could not prepare a report.

Installing the sensor on a MAC

You can install the Qualys Container Sensor on a MAC.

Here are the steps:

Download the QualysContainerSensor.tar.xz file using the “Download and Install Qualys Container Sensor” link on the Get Started page or from the Configurations > Sensors tab on Qualys Cloud Platform.

Copy the file to the target MAC host.

Once you copy the file on the target host, run the following commands in sequence:

This command extracts the tar file.

```
sudo tar -xvf QualysContainerSensor.tar.xz
```

These commands create directories where the sensor data like configuration, manifest, logs, and setup is stored. You can specify a custom location.

```
sudo mkdir -p /usr/local/qualys/sensor/data
sudo mkdir -p /etc/qualys/
```

These commands provide the required permissions to run the installer script.

```
umask 0
chmod -R 777 /usr/local/qualys/sensor/data/*
chmod -R 777 /etc/qualys/
```
The paths `/etc/qualys` and `/usr/local/qualys/sensor/data` should be shared from MAC OS and should be known to Docker. On your MAC host, go to Docker > Preferences > File Sharing, then add the paths `/etc/qualys` and `/usr/local/qualys/sensor/data`, and click **Apply & Restart**.

This command installs the sensor on the host. Notice that it includes the Activation ID and your Customer ID, both generated based on your subscription. The Storage parameter specifies where to install the sensor. Ensure that the HostIdSearchDir exists, otherwise the installer script will throw an error.

```
./installsensor.sh ActivationId=d5814d5f-5fd2-44ec-8969-e03cc58a4ef5
CustomerId=6f35826e-4430-d75e-8356-c444a0abb31
Storage=/usr/local/qualys/sensor/data  LogLevel=4
HostIdSearchDir=/etc/qualys/ ConcurrentImageScan=2 ConcurrentContScan=2
```

**Deploying Sensor in Kubernetes**

Integrate the Container Sensor into the DaemonSet like other application containers and set the replication factor to 1 to ensure there is always a sensor deployed on the Docker Host. This information is applicable for both AWS and GCE.

Perform the following steps for creating a DaemonSet for the Qualys sensor to be deployed in Kubernetes.

Download the `QualysContainerSensor.tar.xz` file from Qualys Cloud Portal and then copy it to Kubernetes master.

Untar the sensor package:

```
sudo tar -xvf QualysContainerSensor.tar.xz
```

Modify the `cssensor-ds.yml` file to provide values for the following parameters:
Appendix
Deploying Sensor in Kubernetes

Under `env` specify the following:

Activation ID (Required)

```
- name: ACTIVATIONID
  value: XXXXXXXX-XXXX-XXXX-XXXX-XXXXXXXXXXXX
```

Customer ID (Required)

```
- name: CUSTOMERID
  value: XXXXXXXX-XXXX-XXXX-XXXX-XXXXXXXXXXXX
```

Specify proxy information, or remove if not required:

```
- name: qualys_https_proxy
  value: proxy.localnet.com:3128
```

Under `volumes` specify the proxy cert path, or remove if not required:

```
- name: proxy-cert-path
  hostPath:
    path: /root/cert/proxy-certificate.crt
    type: File
```

If you are using a proxy, ensure that all Kubernetes nodes have a valid certificate file for the sensor to communicate with the Container Management Server.

If you are not using a proxy and you have removed the above mentioned parts, you can remove the following part from `volumeMounts` as well:

```
- mountPath: /etc/qualys/qpa/cert/custom-ca.crt
  name: proxy-cert-path
```

Ensure that all Kubernetes nodes have the latest Qualys sensor image as mentioned under `spec` or all nodes are able to access the latest sensor image from the registry URL provided.

```
containers:
  - name: qualys-container-sensor
    image: gcr.io/qvta/qualys_sensor:latest
    args: [--k8s-mode]
```

Once you have modified the `cssensor-ds.yml` file, run the following command on Kubernetes master to create a DaemonSet:

```
kubectl create -f cssensor-ds.yml
```

If you need to uninstall Qualys Container Sensor, run the following command on Kubernetes master:

```
kubectl delete -f cssensor-ds.yml
```
Deploying Sensor in Docker Swarm

Integrate the Container Sensor into the DaemonSet like other application containers and set the replication factor to 1 to ensure there is always a sensor deployed on the Docker Host. This information is applicable for both AWS and GCE.

Perform the following steps for creating a DaemonSet for the Qualys sensor to be deployed in Docker Swarm.

Download the `QualysContainerSensor.tar.xz` file from Qualys Cloud Portal and then copy it to Docker Swarm master/leader.

Untar the sensor package:

```
sudo tar -xvf QualysContainerSensor.tar.xz
```

Modify the `cssensor-swarm-ds.yml` file to provide values for the following parameters:

Under **environment** specify the following:

```
environment:
  ACTIVATIONID: XXXXXXXX-XXXX-XXXX-XXXX-XXXXXXXXXXXX
  CUSTOMERID: XXXXXXXX-XXXX-XXXX-XXXX-XXXXXXXXXXXX
  qualys_https_proxy: proxy.qualys.com:3128
```

Activation ID and Customer ID are required. You can remove the proxy information if not required.

Under **volumes** ensure that you provide the following information:

```
volumes:
- type: bind
  source: /var/run/
  target: /var/run/
- type: volume
  source: persistent-volume
  target: /usr/local/qualys/qpa/data/
- type: bind
  source: /etc/qualys  # Must exist!
  target: /usr/local/qualys/qpa/data/conf/agent-data
```

Keep source as "persistent-volume". This ensures that the source directory in volume mapping is set to docker swarm root directory (i.e. /data/docker/volumes)

*/etc/qualys* directory must exist on all masters and worker nodes for successful volume mapping.

```
volumes:
persistent-volume:
```

Under **configs** ensure that you provide the following information:
Appendix
Deploying Sensor in Docker Swarm

configs:
  proxy-cert-path:
    file: /root/cert/proxy-certificate.crt

If you are using a proxy, ensure that all masters and worker nodes have a valid certificate file for the sensor to communicate with the Container Management Server.

If you are not using a proxy and you have removed `qualys_https_proxy` from environment, you can remove the following parts as well:

```yaml
configs:
  - source: proxy-cert-path
    target: /etc/qualys/qpa/cert/custom-ca.crt
```

Ensure that all masters and worker nodes have the latest Qualys sensor image as mentioned under `spec` or all nodes are able to access the latest sensor image from the registry URL provided.

```yaml
qualys-container-sensor:
  image: qualys/sensor:1.1.1
  deploy:
    mode: global  # Deploy 1 container on each node == DaemonSet
    command: ["--swrm-mode"]
```

Once you have modified the `cssensor-swarm-ds.yml` file, run the following command on docker swarm master/leader to create a stack:

```bash
docker stack deploy -c cssensor-swarm-ds.yml qualys-container-sensor
```

If you need to uninstall Qualys Container Sensor, run the following command on docker swarm master/leader:

```bash
docker stack rm qualys-container-sensor
```
